Justin Espiritu Assignment 5

### 1.

Given the public key (7, 143) N = 143, e = 7

First found 2 prime numbers multiplied that equal, 143. In this case 11 and 13.

Then had to find  $\phi$ , which is  $(11-1)(13-1)=120, \phi=120$ 

Given that the inverse is between 100 and 105, I narrowed it down to 101 and 103 as they are the only prime numbers out of those.

 $101 * e = 707 \Rightarrow 707 \mod 120 = 107$ , 101 is not an inverse.

 $103 * e = 712 \Rightarrow 712 \mod 120 = 1$ , 103 is an inverse.

So now we have N = 143, e = 7, phi = 120, d = 103 Cipher or C = 106

decryption =  $C^d \mod 143 = 106^103 \mod 143 = 24$ 

Therefore the decrypted message is 24.

# 2.

### **a**)

yes, the function performs at O(nlog(n)) or  $O(n^3)$  which O(nlog(n)) still fits into the ceiling of O(nlog(n))

#### b)

no, the function performs at  $\Omega(nlog(n))$  or  $\Omega(n^3)$  which both do not satisfy  $\Omega(nlog(n))$  therefore it is no

#### $\mathbf{c}$ )

no, because the function performs at O(nlog(n)) or  $O(n^3)$  which O(nlog(n)) does is not  $O(n^3)$  as it's below that ceiling

### d)

yes, the function performs  $\Omega(nlog(n))$  or  $\Omega(n^3)$  which both fit into the floor of  $\Omega(n^3)$ , which satisfies both

### b)

21 times

#### **c**)

$$\begin{array}{lll} \text{algorithm} & \Theta \\ \text{m} = \mathbf{a}[0] & 1 \\ \text{i loop} & n \\ \text{s} = 0 & n*1 \\ \text{j loop} & n*(n-i) \\ \text{s} = \mathbf{s} + \mathbf{a}[\mathbf{j}] & n*(n-i)*1 \\ \text{s} \ \vdots \ \text{m} & n*(n-i)*1 \\ \text{m} = \mathbf{s} & n*(n-i)*1 \end{array}$$

 $\Theta(n^2)$ , shown by the table above. J loop will happen n-i times which also includes everything, inside of it will also happen n-i times. We then multiply the individual  $\Theta$  times with the times it happens according to the loop they are in. We will then add all the  $\Theta$  times together. From there we can simplify to the highest  $\Theta$ , which in this case is n\*(n-i)\*1 which then can be simplified to just  $\Theta(n^2)$ .

| s = s + a[i]            | 6            | 6            |  |
| s = s + a[i]            | -7           | 6            |  |
| s = 0                   | 0            | 6            |  |
| s = s + a[i]            | 8            | 6            |  |
| m = s                   | 8            | 8            |  |
| s = s + a[i]            | 11           | 8            |  |
| m = s                   | 11           | 11           |  |
| s = s + a[i]            | 20           | 8            |  |
| m = s                   | 20           | 20           |  |
| s = s + a[i]            | 8            | 20           |  |
| final value of $m = 20$ |              |              |  |

## b)

$$\begin{array}{lll} {\rm algorithm} & \Theta \\ {\rm m} = {\rm a}[0] & 1 \\ {\rm i} \ {\rm loop} & n \\ {\rm s} = 0 & n*1 \\ {\rm s} = {\rm s} + {\rm a}[{\rm j}] & n*1 \\ {\rm s} > {\rm m} & n*1 \\ {\rm m} = {\rm s} & n*1 \\ {\rm s} < 0 & n*1 \\ {\rm s} = 0 & n*1 \end{array}$$

 $\Theta(n)$ , shown by the table above. Similar to problem 3, m=a[0] will happen at  $\Theta(1)$ , everything inside the loop will happen n times their theta, which in this case everything inside performs at  $\Theta(1)$ . This results in the highest  $\Theta$  to be n\*1 which can be simplified to  $\Theta(n)$
